Gender-Based Violence and Institutional Responses in Urban Settings

Beatrice Louise Ashford

Abstract:
Gender-based violence undermines personal safety, health, economic independence, and participation in urban life. Although cities may concentrate healthcare facilities, legal institutions, and social services, their availability does not guarantee accessible or coordinated protection. This article examines gender-based violence and institutional responses in urban settings through a narrative review of twelve scholarly and institutional sources published before 2023. It considers the interaction of gender inequality, household relationships, public-space conditions, and institutional practices. Particular attention is given to barriers to disclosure, survivor-centred services, coordination across agencies, and prevention through urban governance. A graph presents published global estimates of intimate partner violence as background evidence, while an analytical table identifies institutional responsibilities and proposed evaluation indicators. The article argues that effective responses require accessible services, respect for survivor autonomy, accountable justice procedures, and sustained prevention. Physical improvements to urban environments should accompany measures addressing discriminatory norms and institutional failures. Progress should be assessed through safety, service quality, equitable access, and survivor-defined outcomes rather than relying exclusively on complaint or prosecution counts.
Keywords: *Gender-based violence, Urban settings, Institutional responses, Survivor-centred services*

Introduction:

Gender-based violence encompasses harmful acts associated with gender inequalities and expectations, including physical, sexual, psychological, and economic abuse. This article concentrates on violence against women and girls while recognizing that gender-based violence also affects people of other genders. In urban settings, violence may occur within households, workplaces, educational institutions, transport systems, public spaces, and digital environments. These settings are connected: abuse within a household can restrict a woman's ability to travel or work, while harassment during a journey can limit access to employment and public services. Cities may offer a comparatively dense network of institutions, but proximity alone does not ensure protection. Transport costs, inaccessible buildings, language barriers, fear of retaliation, uncertainty about procedures, and distrust of authorities can prevent survivors from obtaining assistance. Urban policy must therefore examine both the distribution of violence and the

conditions under which institutional support becomes usable. Heise's (1998) ecological framework provides a basis for understanding interactions across individual, relationship, community, and societal levels. This perspective discourages explanations that locate violence entirely within individual behaviour or attribute it automatically to particular neighbourhoods. The World Health Organization's guidance similarly identifies the importance of evidence-informed healthcare responses within broader systems of support. Drawing on twelve sources published before 2023, this article develops a narrative synthesis rather than reporting original fieldwork or a systematic review. Its five sections examine urban contexts, the interpretation of prevalence and reporting, institutional services, public-space prevention, and accountability. The central argument is that reducing violence requires coordinated institutions that protect autonomy, respond without discrimination, and address the social conditions supporting abuse. Urban safety should consequently be understood through women's ability to live, travel, work, and participate without violence, alongside the quality of assistance available when harm occurs.

Gender Inequality and the Urban Context of Violence:

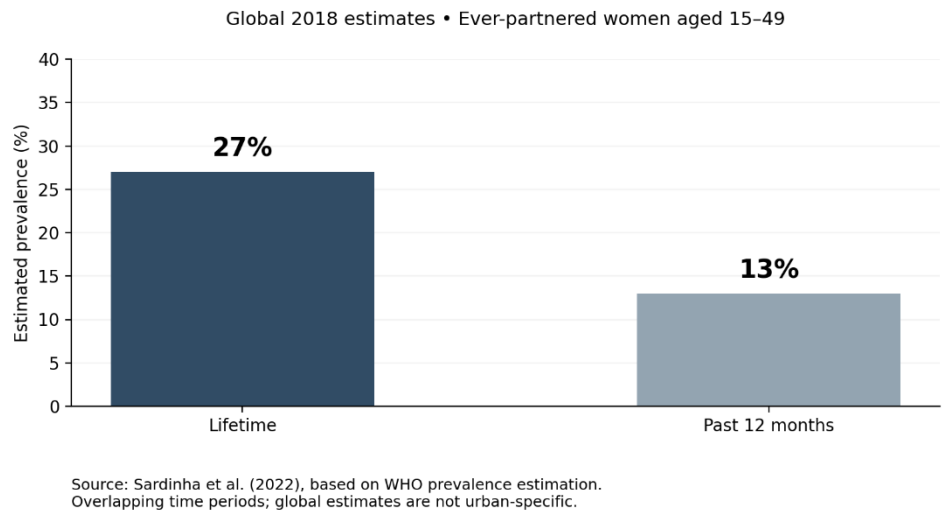
Urban environments influence where violence occurs, how survivors seek help, and which institutions can respond. Housing insecurity may make leaving an abusive household difficult, while transport arrangements can determine whether services are reachable. Employment conditions may expose women to harassment or make time away from work financially costly. These circumstances can constrain choices without explaining or excusing a perpetrator's conduct. Responsibility for violence remains with the person committing it. The ecological approach developed by Heise (1998) examines violence through interacting levels of social organization. Applied to cities, it supports consideration of household power, peer expectations, institutional conduct, and wider norms together. For example, a transport complaint system may exist formally, but its usefulness depends on whether staff take reports seriously, whether passengers can identify the relevant operator, and whether the process protects confidentiality. An institutional response is therefore embedded in social relationships rather than functioning independently of them. Jewkes (2002) examines the causes and prevention of intimate partner violence, emphasizing the importance of understanding the conditions associated with abuse. In an urban analysis, this requires distinguishing contextual pressures from deterministic explanations. Poverty does not make violence inevitable, and abuse is not confined to disadvantaged neighbourhoods. Affluent households and well-resourced institutions can also conceal violence. Policy should avoid stigmatizing locations or assuming that social status reliably predicts safety. The boundary between private and public violence is analytically useful but incomplete. A woman experiencing coercive control may have restrictions placed on her employment, movements, or communication. Public harassment can similarly affect household decisions about travel and participation. Institutions should therefore consider how different forms of harm interact rather than designing support around isolated locations. Differences among women also matter. Age, disability, migration status, income, ethnicity, and language can influence exposure, credibility judgments, and access to services. A programme described as citywide may still exclude people who cannot use its dominant language or reach its service points. Local assessments should involve diverse groups of women and examine practical barriers. The aim is to understand how urban arrangements distribute safety and support while maintaining accountability for abusive conduct.

Prevalence, Underreporting, and the Interpretation of Evidence:

Reliable evidence is essential for planning services, but different data sources measure different phenomena. Population surveys estimate reported experiences among a defined population. Police records document incidents brought to authorities and recorded under particular procedures. Healthcare records describe encounters within services. These sources can

complement one another, but none should automatically be treated as a complete measure of violence.

Global prevalence estimates of physical and/or sexual intimate partner violence



Sardinha et al. (2022) estimated that 27% of ever-partnered women aged 15–49 had experienced physical and/or sexual intimate partner violence during their lifetime, with an uncertainty interval of 23–31%. The corresponding past-year estimate was 13%, with an uncertainty interval of 10–16%. These estimates demonstrate the scale of one important form of violence but do not represent all gender-based violence or establish the prevalence in a particular city. PMC The World Health Organization's *Violence Against Women Prevalence Estimates, 2018* provides a broader foundation for understanding the populations, definitions, and estimation procedures involved. who.int Urban studies should apply similarly explicit definitions. A survey of street harassment, for instance, cannot be directly compared with police records of sexual assault without considering differences in conduct, population, and reference period. Disclosure may depend on privacy, confidence in institutions, fear of consequences, and the way questions are asked. Administrative trends therefore require careful interpretation. Increased complaints can indicate greater violence, improved access to reporting, better recording, or some combination. Reduced complaints may reflect improvement, but they may also signal declining trust or new barriers. Institutional evaluation should investigate these possibilities rather than treating complaint counts as self-explanatory. Cities can improve evidence through ethically designed surveys, service assessments, and consultation with survivors and community organizations. Data collection should minimize unnecessary personal information and protect participants from identification. Findings should guide resources and service improvement without exposing individual survivors or stigmatizing neighbourhoods. The objective is evidence that is useful for prevention and response while respecting the safety and autonomy of those whose experiences inform it.

Survivor-Centred Services and Coordination across Institutions:

A survivor-centred response respects a person's dignity, choices, confidentiality, and particular circumstances. It requires institutions to explain available options, avoid blame, and provide support without unnecessarily compelling repeated disclosure. Respecting autonomy does not mean leaving survivors to navigate fragmented services alone. It means offering practical assistance while explaining the boundaries of confidentiality and any applicable legal duties. The WHO's clinical and policy guidelines establish an evidence-informed basis for healthcare

responses to intimate partner and sexual violence. who.int At the institutional level, this requires privacy, trained personnel, appropriate documentation, and usable referral arrangements. A protocol has limited value if staff lack time, facilities, or continuing support to implement it. Services should assess these operational conditions alongside professional training. The *Essential Services Package for Women and Girls Subject to Violence* connects health, policing, justice, social services, and coordination. United Nations Population Fund Its relevance to cities lies in the need to turn the concentration of agencies into a coherent response. Referring someone to another institution is insufficient if that institution is unavailable, unaffordable, or unable to provide the required assistance.

Table 1. Institutional responsibilities in an urban response

Institution or service	Core responsibility	Common implementation problem	Proposed evaluation indicator
Healthcare services	Provide appropriate care, first-line support, and referral	Limited privacy or unclear procedures	Availability of private consultations and functioning referrals
Police services	Receive reports respectfully and respond to risk	Dismissal, delay, or inconsistent recording	Response quality and documented follow-up
Justice institutions	Provide accessible procedures and remedies	Costs, delays, or inaccessible information	Access to assistance and procedural timeliness
Social services and shelters	Support safety, accommodation, and practical needs	Insufficient capacity or restrictive eligibility	Access, continuity, and unmet demand
Transport and municipal authorities	Address public-space and transport concerns	Weak complaint systems or poor maintenance	Complaint resolution and user-assessed safety
Community organizations	Provide trusted support and identify access barriers	Insecure funding or weak referral links	Continuity of support and reach among underserved groups

García-Moreno et al. (2015) emphasize that health-system responses depend on protocols, capacity building, coordination, and referral networks. PubMed Building on this approach, coordination should include named responsibilities, current service information, and procedures for checking whether assistance was obtained when appropriate and consented to. Information sharing should be limited to what is necessary and permitted. A shared database is not automatically safer or more effective than a carefully managed referral process. Urban services should also accommodate disability, language differences, childcare needs, and employment constraints. Accessibility is demonstrated through practical use rather than the formal existence of a programme. Survivors' assessments of whether they were respected, informed, and supported should therefore inform institutional improvement.

Public-Space Safety, Urban Planning, and Primary Prevention:

Urban prevention should address violence in public spaces while recognizing that environmental improvements alone cannot resolve gender inequality. Lighting, transport reliability, accessible facilities, and the maintenance of public areas can affect how people navigate a city. Their design should be informed by women's experiences and tested in context. No particular physical intervention should be presented as a universal guarantee of safety. UN Women's *Safe Cities and*

Safe Public Spaces work connects local evidence, public-space interventions, institutional action, and participation by women and girls. Its 2017 report provides examples of efforts to address sexual harassment and related violence in urban environments. unwomen.org A central implication is that planners should ask how proposed changes affect actual journeys and activities. Improvements around a transport station, for example, may have limited benefit if connecting routes remain difficult to use. Participation should include women who use public space under different conditions. Street vendors, domestic workers, students, older women, and persons with disabilities may identify different concerns. Consultation should lead to decisions, budgets, and follow-up rather than functioning only as a symbolic exercise. Authorities should explain what was changed and how outstanding problems will be addressed. The global results report covering 2017–2020 documents further initiatives concerned with women's safety and autonomous mobility. unwomen.org Such programme reports are valuable for identifying approaches and implementation experiences, but they should not automatically be interpreted as proof that every intervention caused a reduction in violence. Evaluation designs, local conditions, and outcome definitions must be examined. Primary prevention also addresses the attitudes and practices that support abuse. The WHO's *RESPECT Women* framework brings together strategies concerning relationships, empowerment, services, poverty, safer environments, childhood and adolescent abuse prevention, and transformed attitudes and norms. Preventing violence against women Cities can connect these priorities through schools, workplaces, community organizations, and public institutions. Prevention should expand freedom rather than place additional restrictions on women. Measures that advise women to avoid work, travel, or public activities may transfer responsibility to potential victims. Effective planning asks how institutions can reduce harmful conduct and improve accountability while preserving equal access to urban opportunities.

Institutional Accountability, Legal Frameworks, and Evaluation:

Institutional accountability requires a clear relationship between commitments, resources, professional conduct, and outcomes. Laws and policies establish important expectations, but implementation depends on procedures, staffing, budgets, and oversight. A city may endorse a strategy while leaving services unable to deliver it. Evaluation should therefore assess institutional capacity and the experience of service users alongside formal policy adoption. UN Women's *Handbook for Legislation on Violence Against Women* offers a framework for examining legal responses. un.org Its relevance here is institutional: legal protections need accessible information, appropriate assistance, and consistent implementation. Specific duties and remedies vary across jurisdictions, so cities should map the applicable framework rather than assume that a single legal model applies universally. Responsibility should be assigned clearly across agencies. Municipal authorities may influence transport, public facilities, local planning, and service funding, while policing and justice responsibilities may lie elsewhere. Coordination mechanisms should reflect these actual powers. Regular meetings have limited value unless decisions produce action and unresolved problems can be escalated to an accountable body. Ellsberg et al. (2015) review evidence concerning prevention interventions and identify the importance of examining what works through rigorous research. PubMed Applied to urban programmes, this supports distinguishing implementation outputs from substantive outcomes. Training counts, campaign reach, and facility improvements document activity. Changes in violence, equitable service access, and women's freedom to participate concern outcomes. Both are necessary, but they answer different questions. Evaluation should combine quantitative and qualitative evidence. Surveys can examine experiences over time, while interviews and service reviews can explain barriers and implementation failures. Comparisons should consider population changes, recording practices, and alternative explanations. Where causal attribution is not supported, reports should describe associations and implementation findings accurately.

Accountability also includes safe ways to challenge institutional conduct. Complaints procedures should be accessible, protect confidentiality, and provide a response within clearly communicated timeframes. Staff support and supervision should accompany sanctions for misconduct. The purpose is an institutional culture in which respectful treatment is routine and failures generate correction. Sustained financing is essential. Short campaigns cannot substitute for reliable services and continuing prevention. Budgets should reflect identified needs, and progress reports should explain both achievements and remaining gaps. Institutional success is best understood through improved safety, agency, service quality, and equal access to city life.

Summary

Gender-based violence in urban settings is shaped by relationships between gender inequality, household conditions, public environments, and institutional practices. Cities can concentrate services and opportunities while still leaving substantial barriers to effective protection. The article has distinguished violence prevalence from recorded complaints and emphasized that administrative changes require careful interpretation. The graph provides global background estimates of physical and sexual intimate partner violence, rather than urban-specific findings or a comprehensive measure of gender-based violence. Institutional responses should connect healthcare, policing, justice, social support, municipal authorities, and community organizations through practical referral arrangements and clear responsibilities. Survivors' dignity, autonomy, confidentiality, and access needs should guide these processes. Public-space improvements can support safer mobility, but their value depends on context and should be assessed alongside efforts to address abusive conduct and discriminatory norms. Prevention must strengthen women's freedom to participate in urban life rather than restrict their movements or transfer responsibility for violence onto them. Accountability requires sufficient resources, accessible complaint mechanisms, consistent professional conduct, and evaluation that distinguishes activities from outcomes. Because this article is a narrative review, it identifies principles and mechanisms without claiming a universal causal effect for particular policies. Future urban research should investigate variation across neighbourhoods and social groups, evaluate coordinated interventions, and include survivor-defined measures of progress. A durable response combines prevention, accessible support, fair institutional processes, and sustained public responsibility. Urban safety becomes meaningful when women and girls can exercise their rights and obtain effective assistance without discrimination, avoidable barriers, or loss of autonomy.
